Abstract: In the present study, the ballistic impact resistance of kevlar reinforced polymer composites and shape memory alloy sheet reinforced kevlar epoxy polymer composites have been compared numerically and experimentally. The test specimens have been fabricated by the hand layup method, and the ballistic impact test has been conducted according to NIJ Level IIIA. In the current research, a new method has been proposed to measure the ballistic impact resistance of the material by using Image J software. From the test results, it has been observed that reinforcement of shape memory alloy in kevlar epoxy polymer composites has increased the ballistic impact resistance by 89-145% for the damaged area compared with plain kevlar reinforced epoxy polymer composite. Also, the damaged area observed in the numerical and the experimental results is almost the same.

Keywords: ballistic, delamination, fiber, kevlar, nitinol.

Introduction

The development process of armor material for ballistic applications had its focus on reducing the weight of the armor and improving the ballistic impact resistance. The selection of the armor material was to have increased toughness, good stiffness, light weight, and low cost. The current research focuses on improving the ballistic resistance of kevlar epoxy polymer composites by reinforcing shape memory alloy (SMA) in the form of sheet in the polymer composite. Many researchers have carried out many kinds of research to improve the ballistic impact resistance, and some of them are briefly presented below.

The present study aims at evaluating the ballistic impact properties of plain kevlar reinforced epoxy polymer composite and shape memory alloy sheet reinforced kevlar epoxy polymer composite. Ahmadi et al., investigated the high-velocity impact of glass fiber metal laminate composites. They reported delamination between the glass fabric reinforcement layers and that no such delamination was observed between the aluminium sheet reinforcement and glass fabric. Park et al., stated that impregnation of shear thickening fluid in kevlar fabric affected the back face signature and perforation ratio. Also, they reported that the ballistic impact energy dissipated into kinetic
energy dissipation and tensile energy dissipation. Zhang et al.,\textsuperscript{10} investigated experimentally and analytically the oblique high-velocity impact of fiber metal laminates. Also, they reported that the impact angle and the initial velocity influenced the deflection of the projectile.

From the brief literature survey, it can be observed that fiber metal laminates improve the ballistic impact\textsuperscript{8-10} resistance of the composite. The current research also employs shape memory alloy in kevlar epoxy polymer composites to improve the ballistic impact resistance.

**Experimental**

**Materials and Fabrication.** The test specimens were fabricated from kevlar fabric of 400 gsm and with a density of 1.44 gm/cm\textsuperscript{3} using epoxy resin CT/E-120 of 1.2 gm/cm\textsuperscript{3} density. The epoxy resin\textsuperscript{11-14} and the hardener CT/Ah-60 were mixed in the ratio of 10:1 for fabrication. The composites were fabricated by the hand layup method to improve the bonding\textsuperscript{14} between the reinforcement and the matrix. For shape memory alloy sheet reinforced kevlar epoxy polymer composites, the SMA sheet was stacked in the middle layer of kevlar fabric stacking and epoxy resin mixed with hardener was applied as adhesive. The samples were fabricated to a size of 300 mm×300 mm and the edges of the test specimens were obtained using the abrasive water jet machining process.

The specimens were stacked as [Kevlar/Kevlar], [Kevlar/SMA Sheet/Kevlar]. The kevlar fabric was stacked one above the other and in each layer, a coating of epoxy resin was applied to enhance the bonding between the stacked kevlar fabrics.

**Figure 1.** Plain kevlar and SMA Sheet reinforced kevlar stacking sequence.

**Figure 2.** Ballistic impact simulation test conditions.

**Numerical Analysis.** The composite laminate for ballistic impact analysis was designed using creo software and the following mechanical properties\textsuperscript{15-19} were assigned for kevlar fabric and shape memory alloy reinforcement. The test conditions are shown in Figures 5.31 and 5.32 for plain kevlar reinforced epoxy polymer composite and SMA Sheet Reinforced kevlar epoxy polymer composite.

The numerical analysis was carried out by ANSYS 19.2 version software. The 3D model of the bullet and the samples were prepared by using Creo 5.0 version software. The 3d modeled bullet and the samples are shown in the below Figure. The meshing applied was tetra and hexa mesh for the analysis. The friction coefficient between the reinforcements was assigned as 0.4. The tensile yield strength of the kevlar fabric was assigned as 1.85 GPa and the compressive yield strength of the kevlar fabric assigned was 0.185 GPa and the ballistic impact\textsuperscript{20} test was conducted at 440 m/sec at NIJ Level IIIA. The test conditions assigned for plain kevlar epoxy polymer composite and SMA sheet reinforced kevlar epoxy polymer composite are
shown in the below Figure. The assigned material properties of kevlar reinforced epoxy polymer composite, shape memory alloy sheet reinforcement and brass bullet are listed in Table 1.

**Ballistic Impact Test.** The ballistic impact test was conducted at Ballistic Research Centre and Testing Range at National Forensic Sciences University, Gujarat. The ballistic impact test was conducted according to NIJ Level IIIA at 430 m/sec. The target panel was mounted on a fixture and the sample was fabricated to a size of 300 mm×300 mm. The bullet used for testing was 9 mm and 19 mm in length, the firing distance was set at 5 m, and the angle of firing was set at 90°. Three samples of plain kevlar reinforced polymer composite and SMA sheet reinforced kevlar epoxy composite were tested and the results obtained are discussed below.

### Results and Discussion

**Theoretical Analysis.** Park et al.⁹ have stated that incident ballistic impact gets dissipated into kinetic energy and tensile energy. Also, they have said that specific energy absorption can be calculated from the below formula.

$$\frac{1}{2} m v_{50}^2 = E_t + E_k$$  \hspace{1cm} (1)

where $E_t$ and $E_k$ are tensile and kinetic energy dissipation.

Specific energy absorption = $\frac{1}{2} \frac{m v_{50}^2}{\text{areal density}}$  \hspace{1cm} (2)

**Numerical Analysis.** The damaged area due to the ballistic impact was measured by using Image J freeware software. It is image processing software, which analyzes the image pixel by pixel based on the contrast level. In the current research, the damaged area was analyzed in terms of pixels and the amount of pixels in a particular region was used to measure the damaged area, which is the proposed method for measuring the ballistic impact resistance. The increase/decrease in the damaged area can be used to measure the decrease/increase in ballistic impact resistance of the material.

The numerical results were analyzed using image j software. The image J analysis software was used for studying the ballistic impact areas of the samples. To measure the damaged area the image of the sample was uploaded and the measurement scale had to be set for measuring the damaged area.

**Plain Kevlar Reinforced Epoxy Polymer Composite:** From the simulation test results, they found that for plain kevlar epoxy polymer composite the deformation observed was 1.3374 mm for the top layer. Also, the deformation observed for the bottom layer was 0.1255 mm. No penetration was observed in the composite specimen and deformation was higher in the bottom layer compared with the top layer of the specimen.

**SMA Sheet Reinforced Kevlar Epoxy Polymer Composite:** From the simulation test results, they found that for SMA sheet reinforced kevlar epoxy polymer composite the deformation observed was 1.1304 mm for the top layer. Also, the deformation observed for the bottom layer was 0.1609 mm. No penetration was observed in the composite specimen and deformation was higher in the bottom layer compared with the top layer of the specimen.

**Figure 3.** Ballistic impact test setup.

**Figure 4.** Damaged area for plain kevlar epoxy polymer composite at the top and the bottom layers.
Ballistic Impact Test. Damage Absorbing Mechanisms:
During the ballistic impact, the incident kinetic energy of the bullet was transferred to the test specimen during impact and this energy would be absorbed in various forms. The energy absorption would occur till all the kinetic energy from the bullet was absorbed by the specimen till it reached zero and indentation would occur in the specimen with various failure mechanisms. And in case the initial kinetic energy of the bullet exceeded the energy absorbed by the specimen, the bullet would penetrate. The failure mechanisms commonly observed were stretching and deformation of primary and secondary yarns, shear plugging, matrix cracking, delamination, and conical shape deformation at the back face of the test specimen.

Plain Kevlar Reinforced Epoxy Polymer Composite:
During the ballistic impact of plain kevlar reinforced epoxy polymer composite, it was found that sample had some penetration and the damaged area in the impact surface was 246.92 mm² while the damaged area at the backside of the impact area was 1036.40 mm². The results of the front and back damaged areas obtained in the ballistic impact test compared with the numerical results were 99.19% and 99.04% accurate. A partial penetration was observed at the front face of the composite structure due to the ballistic impact and a shear plug was observed at the back face of the composite.

SMA Sheet Reinforced Kevlar Epoxy Polymer Composite:
During the ballistic impact of SMA sheet reinforced kevlar epoxy polymer composite, it was found that the sample had some penetration and the damaged area on the impact surface was 100.44 mm² and the damaged area at the backside of the impact area was 546.24 mm². It was also observed that with the reinforcement of the SMA sheet in plain kevlar epoxy polymer composite, the front damaged area was reduced by 89.73% and the back side damaged area was reduced by 99.04%.

Figure 5. Damaged area for SMA Sheet reinforced kevlar epoxy polymer composite at the top and the bottom layers.

Figure 6. Damaged area of Plain kevlar reinforced epoxy polymer composite.

Figure 7. Damaged area of SMA Sheet reinforced kevlar epoxy polymer composite.
The front and the back damaged area results obtained in the ballistic impact test compared with the numerical results were 98.13% and 98.14% accurate. A partial penetration was observed at the front face of the composite structure due to the ballistic impact and a shear plug was observed at the back face of the composite. But it was comparatively smaller than the shear plug observed for ballistic impact on plain kevlar epoxy polymer composite. The reason for the decrease in the damage area is the energy absorption capacity and impact resistance offered by the shape memory alloy.

Morphological Analysis. The morphological analysis revealed the potential failure mode observed during the ballistic impact test. The major mechanisms observed were fiber cracking, matrix cracking, and delamination. Also, excellent fiber and matrix bonding was observed between the fiber and the matrix which increased the ballistic impact resistance of the material.

145.84%. The front and the back damaged area results obtained in the ballistic impact test compared with the numerical results were 98.13% and 98.14% accurate. A partial penetration was observed at the front face of the composite structure due to the ballistic impact and a shear plug was observed at the back face of the composite. But it was comparatively smaller than the shear plug observed for ballistic impact on plain kevlar epoxy polymer composite. The reason for the decrease in the damage area is the energy absorption capacity and impact resistance offered by the shape memory alloy.

Morphological Analysis. The morphological analysis revealed the potential failure mode observed during the ballistic impact test. The major mechanisms observed were fiber cracking, matrix cracking, and delamination. Also, excellent fiber and matrix bonding was observed between the fiber and the matrix which increased the ballistic impact resistance of the material.

Conclusion

In the current study, the ballistic impact analysis of kevlar reinforced polymer composite and shape memory alloy reinforced kevlar epoxy polymer composite was carried out and the following observations are presented below:
· The failure mechanisms observed during the ballistic impact testing were delamination, fiber cracking, and matrix cracking.
· Addition of shape memory alloy sheet in kevlar epoxy polymer composite increases the ballistic impact resistance by 89%-145%.
· Further research can be carried out in improving the surface of the shape memory alloy to improve the resistance to delamination.
